BACK-END OVERVIEW

- The system uses the users and listings tables as the initial database foundation for UniMart. It stores profile information such as user ID, username, full name, email, account type, student number, university, and campus.
- This allows the system to identify users, separate platform roles, and support the university specific trust model required.
- Authentication details such as passwords are not stored in this table because the system uses a third-party identity provider for secure login

- The listings table is included to prepare the system for later app/web functionality. Although our main focus right now is on login, the app/web's main purpose is to allow students to buy, sell, and trade items.
- The listings table stores information about items posted on the platform, including the title, description, price, category, condition, tradeable status, and listing status.
- The seller_id field links each listing to a user in the users table, ensuring that every listing belongs to a registered account. This relationship is important for future user stories involving creating, editing, deleting, searching, and managing item listings.

These tables therefore support both the immediate goal of secure user access and the long-term development of the app/web system in future
